Different methods have been grouped together based on their signal output to compare the performances of each microfluidic device. Among all the methods reviewed, the limit of detection (LOD) of most microfluidic detection ranges from 0.01 to 30 000 ng/ml with fluorescence, chemiluminescence, and colorimetry format, depending on the detection ...

To support, supplement, or complement microarrays, standardized or customized microfluidic devices can be useful for rapid sample preparation and screening of samples where labile targets may suffer degradation (especially mRNAs) or low yield (e.g., microRNAs), quality control of reagents, detecting the presence of inhibitor substances and other interfering components, before the samples are subjected to more costly and time-consuming microarray analysis or sequencing.

The probes are synthesized prior to deposition on the array surface and are then "spotted" onto glass. A common approach utilizes an array of fine pins or needles controlled by a robotic arm that is dipped into wells containing DNA probes and then depositing each probe at designated locations on the array surface.

Today, there are a few reports tackling these challenges, for example, by improving current detection methods, using electrochemical assays 7, 8 or developing pH-based POC tests. 9 However, these approaches still need error-prone amplification steps prior to the miRNA detection, have rather tedious preparation steps, or are limited by the ...

The early methods had the advantage of easier detection from certain machines like those that measure fluorescence. More recent designs have fully integrated HPLC columns into microfluidic chips. The main advantage of integrating HPLC columns into microfluidic devices is the smaller form factor that can be achieved, which allows for additional features to be combined within one microfluidic chip.
